Research Hypotheses

PDF edition of preserved repository document | docs/research_hypotheses.md

Historical statements and test counts below retain their original scope. Consult the master report for current status.

Research hypotheses

Explicit state-transition learning may improve data efficiency, OOD performance and evidence-supported output in bounded domains. This is untested. Deterministic algorithm performance alone cannot establish learned generalization or superiority.

Compare answer-only supervision (A), trajectory supervision (B), and concept plus limited examples plus environment feedback (C). C must not silently receive full trajectory supervision. Equalize backbones, test sets, examples, decoding, epochs and compute where practical; explicitly report additional procedural knowledge.
